Implementing Drag and Drop in React

Option 1: Using `react-dnd` (flexible, powerful)

Steps (from GeeksforGeeks tutorial):

1. Wrap your app with `DndProvider` and `HTML5Backend`.
2. Create draggable items using `useDrag`.
3. Create drop zones using `useDrop`.
4. Manage dropped items with `useState`.
5. Style drag states (opacity, borders, etc.).

Option 2: Using `dnd-kit` (modern, recommended)

Key concepts:

- **Draggable** components
- **Droppable** areas
- **Sortable** lists
- **Sensors** for mouse, touch, keyboard
- **Modifiers** for constraints (e.g., axis-locking)
  This toolkit is extensible and production-ready.

dndkit.com

Option 3: Native HTML5 Drag Events

Examples include:

- `onDragStart`
- `onDragOver`
- `onDrop`
  React demos show how to reorder lists using only native events and `useState`.

When to Choose Which Library

- **dnd-kit** → Best for modern apps, sortable lists, custom interactions.
- **react-dnd** → Best for complex drag logic, custom backends, game-like interactions.
- **hello-pangea/dnd** → Best for simple list reordering and kanban boards.
- **Native events** → Best for lightweight, dependency-free implementations.

React drag-and-drop solutions continue to evolve, with `dnd-kit` and `react-dnd` remaining the most robust choices for production use.
